# A modification to Paulson's approximation to the variance ratio distribution 

By T. Ashby*

#### Abstract

Paulson's approximation to the variance ratio distribution is poor or useless for less than five degrees of freedom in the denominator. However, it can be modified in this range to give results correct to three significant figures.

(First received November 1967)

Tables of percentage points of the variance ratio distribution $F$ are readily available (e.g. Fisher and Yates, 1963), but are not convenient to use with a digital computer. On the other hand it is not practical to calculate regressions or analyses of variance involving many variables without using a computer, and significance testing is naturally required in such programs. Consequently some way of calculating values of $F$ is required, and an approximation is generally used.

Kendall and Stuart (1958 edition) discuss three such approximations. The third of these is due to Paulson (1942) whose reasoning is first that $F$ can be written as the ratio of two chi-squared variates divided by their degrees of freedom. Secondly, Wilson and Hilferty (1931) have shown that $\left(X^{2} / n\right)^{1 / 3}$ is nearly normally distributed, with mean $1-2 / 9 n$ and variance $2 / 9 n$. Thirdly, Fieller (1932) has shown that if $x$ and $y$ are normally distributed with means $\mu_{x}$ and $\mu_{y}$ and standard deviations $\sigma_{x}$ and $\sigma_{y}$ then a function

$$
R=\frac{\frac{y}{x} \mu_{x}-\mu_{y}}{\left(\left(\frac{y}{x}\right)^{2} \sigma_{x}^{2}+\sigma_{y}^{2}\right)^{1 / 2}}
$$

is approximately normally distributed with zero mean and unit variance. Replacing $y / x$ in this last expression by $F^{1 / 3}$ we obtain

$$
U=\frac{\left(1-2 / 9 n_{2}\right) F^{1 / 3}-\left(1-2 / 9 n_{1}\right)}{\left(2 F^{2 / 3} / 9 n_{2}+2 / 9 n_{1}\right)^{1 / 2}}
$$

where $F$ is the variance ratio and $n_{1}$ and $n_{2}$ are the degrees of freedom in the numerator and the denominator. This function is approximately normally distributed with zero mean and unit variance.

This approximation can of course be rearranged to give approximations to the percentage points of $F$ in terms of normal deviates $U$ and $n_{1}$ and $n_{2}$. We shall call this approximation $P$. If we write $f_{1}$ for $2 / 9 n_{1}$ and $f_{2}$ for $2 / 9 n_{2}$ and solve Paulson's equation as a quadratic in $P^{1 / 3}$ we obtain

$$
\begin{aligned}
& P^{1 / 3}= \\
& \frac{\left(1-f_{1}\right)\left(1-f_{2}\right) \pm\left[u^{2}\left(f_{1}+f_{2}+f_{1} f_{2}\left(f_{1}+f_{2}-u^{2}-4\right)\right)\right]^{1 / 2}}{\left(1-f_{2}\right)^{2}-u^{2} f_{2}}
\end{aligned}
$$

Computer programs store the important values of normal deviates $u$, and from these calculate $P$. The approximation is good for values of $n_{2}$ above 10 but for smaller values is poorer, and for $n_{2}$ up to 3 produces useless and even negative results, as can be seen by comparing Tables 1 and 2.

This difficulty can be overcome, however, by applying a linear transformation $G=m P+c$, where $m$ and $c$ are constants depending on the significance level and on $n_{2}$, the degrees of freedom of the denominator. Suitable values are stored in the computer and $P$ is adjusted whenever $n_{2}$ is below a critical value. This modified approximation gives results which are generally correct to three significant figures, as can be seen by comparing Tables 1 and 3.

Table 1
Variance ratio distribution, $F$
(Fisher \& Yates)

| ${ }_{1}{ }_{1}^{n_{1}}$ | 95\% |  |  | 99\% |  |  | 99.9\% |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2 | 6 | 24 | 2 | 6 | 24 | 2 | 6 | 24 |
|  | 199.5 | $234 \cdot 0$ | $249 \cdot 0$ | 4999 | 5859 | 6234 | 5000* | 5859* | 6235* |
| 2 | $19 \cdot 00$ | $19 \cdot 33$ | 19.45 | 99.00 | $99 \cdot 33$ | $99 \cdot 46$ | $999 \cdot 0$ | $999 \cdot 3$ | 999.5 |
| 3 | $9 \cdot 55$ | $8 \cdot 94$ | $8 \cdot 64$ | $30 \cdot 82$ | $27 \cdot 91$ | $26 \cdot 60$ | $148 \cdot 5$ | $132 \cdot 8$ | $125 \cdot 9$ |
| 4 | $6 \cdot 94$ | $6 \cdot 16$ | $5 \cdot 77$ | $18 \cdot 00$ | $15 \cdot 21$ | 13.93 | $61 \cdot 25$ | $50 \cdot 53$ | $45 \cdot 77$ |
| 5 | $5 \cdot 79$ | $4 \cdot 95$ | $4 \cdot 53$ | $13 \cdot 27$ | $10 \cdot 67$ | $9 \cdot 47$ | $37 \cdot 12$ | $28 \cdot 84$ | $25 \cdot 14$ |
| 10 | $4 \cdot 10$ | $3 \cdot 22$ | $2 \cdot 74$ | $7 \cdot 56$ | $5 \cdot 39$ | $4 \cdot 33$ | $14 \cdot 91$ | $9 \cdot 92$ | $7 \cdot 64$ |

* Multiply these values by 100 .

[^0]$P$ approximates $F$ well above $n_{2}=10$ and is quite good for $n_{2}$ down to 5 . A program testing significance at the $5 \%, 1 \%$ and $0.1 \%$ levels and using the modification for $n_{2}$ up to 5 needs to store 30 extra numbers.

Table 4 gives values of $m$ and $c$ for $n_{2}$ up to 10 , derived empirically. The modified approximation has been programmed in Autocode for the Elliott 803 and in NELIAC for the Univac 490.
